A. Script Idea

Describe the idea and where the script will live on your site (which page). Explain how it enables user interaction and what features of your site will benefit from it.

My idea for where the script will live is on the current trainer page of the website. The plan is to have a script where we calculate the total price of their personal trainer based on the number of sessions, where each session has a number of hours. This will enable user interaction because they are able to see the price quickly, instead of having to do the calculating themselves. The current trainer page would benefit from this since it adds more important and relevant information that the user can have to make decisions.

B. Goals

Outline what you aim to achieve with this script. For example, will the script enhance user experience, provide useful calculations, or display dynamic content based on user input?

The goal of this script is to provide useful calculations, the calculation is the total price for a user's current trainer. The goal is to display dynamic content based on user input. The user gives the amount of hours per session and how many sessions a month. With that information the script will output a price.

C. Task Breakdown

Break down the process into smaller tasks that your script will need to perform. Think through each step, from capturing user input to displaying the final output on the site.

- Pull hourly price from current trainer
- Get user input for hours per session
- Get user input for sessions per month
- Calculate total monthly price for the trainer
- Display calculated price on screen

D. Flowchart

Visualize the steps in your script by creating a flowchart that maps out the sequence of actions. You can use tools like draw.io or any other diagram tool to sketch out the logical flow of your script.
